

On-Board Diagnostics (OBD) Computer

- Standard in 1996 and later vehicles
- Continually monitors the emissions control system to maintain proper engine operation.

OBD Test

- The vehicle's OBD computer is connected to the emissions test unit to directly analyze emissions control system information.
- During vehicle operation, a Diagnostic Trouble Code (DTC) is stored in the onboard computer when an emissions-related fault is found. The OBD test can reveal saved DTCs.

Malfunction Indicator Lamp (MIL)

- "Service Engine Soon" or "Check Engine" dashboard panel light
- Illuminates when the vehicle's OBD computer detects an emissions-related fault.
- Lights up when the vehicle's emissions surpass the certification standards by 50 percent.

Benefits of OBD Test

- Greater accuracy and faster completion
- Analysis using DTCs aids in identifying problems with your vehicle's emission control system for a better diagnosis.
- Immediate detection and correction of engine faults helps avoid expensive repairs in the future, lowers emissions, and provides better performance and fuel economy.

Common Diagnostic Trouble Codes (DTCs) and their causes

Readiness and No Communication

- An OBD test will indicate "Fail for Communication" if the vehicle's OBD system can't provide data.
- The OBD test will indicate "Fail for Readiness" if enough monitors have not executed their checks.
- A monitor is regarded as "Ready" when it has successfully executed a check.
- "Ready" monitors only default to "Not Ready" when battery power has been disconnected for repairs or if the computer memory has been erased.

Getting Your Vehicle Ready

- Monitors will generally become "Ready" after several days of both city and highway driving.
- After a few minutes of normal driving, most vehicles without emissions control system problems will be "Ready", but vehicles with complications may need more time.
- Even when "Ready", emissions problems may be detected during the OBD test, which could return a failure.
